1. What is TaskbarStats?

TaskbarStats is a small, lightweight system monitor for Windows 10 and 11. A tiny widget floats right next to the notification area of your taskbar and shows live **CPU, GPU, memory, network, disks, battery, FPS and temperatures**. Want more? There is a large desktop dashboard and a fullscreen "cockpit" with details, graphs and the full specifications of your PC.

The widget next to the clock: numbers, gauges, bars or graphs (all values in the screenshots are made up).

The three parts

Part	What it is	Open with
Taskbar widget	Small, always visible, next to the notification area. Tooltip with all the details.	Starts automatically
Desktop dashboard	Large translucent window with tiles and graphs of the last 5 minutes; in front or behind your windows, click-through.	Menu, or **Ctrl+Alt+D** (click-through)
Fullscreen cockpit	One dense overview across a whole screen; click a tile for depth. Includes a specifications page and an automatic tour.	**Ctrl+Alt+F**

Why the numbers are right

The values come from the same sources as Task Manager, so you can compare them. Only the temperatures come from a separate library (LibreHardwareMonitor).

Item	Source	Remark
CPU	Windows performance counters (`Processor Information`)	Same value as Task Manager. Optionally the boost-scaled "Utility" measure (almost 2× higher on a boosting CPU).
Memory	`GlobalMemoryStatusEx`	Exactly the percentage Task Manager shows.
GPU	`GPU Engine` performance counters	Per GPU the busiest engine, in line with Task Manager. With two GPUs (iGPU + dGPU) *Automatic* follows the busiest one.
Network	`Network Interface`	Per adapter or all adapters combined.
Temperature	LibreHardwareMonitor	Needs administrator rights. Without a CPU sensor the app falls back to the Windows thermal zone.
Ping	.NET `Ping`	Latency, jitter and packet loss to a target of your choice.
Specifications	WMI, registry, Win32	For the specifications page in fullscreen.

> **Tip** TaskbarStats is frugal: about 2% of one CPU core and roughly 60 MB of memory at rest. When the widget is hidden and the dashboard and fullscreen are closed, the app only measures once every 5 seconds.

2. Installation

What you need

- **Windows 10 or 11**, 64-bit (x64).
- No separate .NET installation: the installer contains everything (a self-contained, compressed build).
- **Administrator rights.** They are needed for the temperature sensors; Windows asks once while installing.
- No account and no internet connection needed (only the optional plugins and the optional update check use the internet).

Step by step

1. Go to **github.com/ericbruggema/TaskbarStats/releases/latest** (or via **taskbarstats.com**, *Download* button).
2. Under *Assets*, download `TaskbarStats-Setup-<version>.exe` and run it.
3. Confirm the Windows prompt (UAC). If the file is not digitally signed, SmartScreen may warn you: choose **More info → Run anyway**.
4. Pick the installer language (Dutch or English).
5. If TaskbarStats is already installed, the installer tells you whether this is an **update**, a **reinstall** or an older version and asks Yes/No before overwriting.
6. Read the Readme (explanation and credits) that the wizard shows.
7. Pick the extra tasks: **desktop shortcut** and **optional plugins** (both off by default).
8. On the *Start with Windows* page choose whether the app starts at logon (default **Yes** for a new installation; an update keeps your current choice).
9. Click *Finish*: TaskbarStats starts and the widget appears left of the notification area. On the first start you see a welcome screen.

The Start menu gets a **TaskbarStats** folder with the app, the Readme, *Uninstall TaskbarStats* and shortcuts to the website and GitHub.

Start with Windows

Because the app asks for administrator rights, the normal Windows Run key does not work. TaskbarStats therefore creates a **scheduled task "at logon" with highest privileges**: you get no UAC prompt when you log in. You can switch it on or off later under *Settings → General → Start with Windows*.

Silent installation (for admins and scripts)

```
TaskbarStats-Setup-1.6.8.exe /SILENT /AUTOSTART=yes
TaskbarStats-Setup-1.6.8.exe /VERYSILENT /AUTOSTART=no /TASKS="plugins"
```

Parameter	Meaning
`/SILENT`, `/VERYSILENT`	Install without the wizard (no overwrite questions).
`/AUTOSTART=yes|no`	Set start with Windows on or off.
`/TASKS="plugins"`	Also install the optional plugins.
`/DIR=...`, `/GROUP=...`	Custom folder / Start menu group. Ignored when there is an existing installation.

Updating

Download the new installer and run it: the old version is closed and replaced, and your settings stay. Want to be told about new versions? Turn on the **update check** (off by default; *Settings* → *General*). It looks at GitHub at most once every 24 hours, only reports that something newer exists, and never downloads or installs anything.

Uninstalling

Start menu → TaskbarStats → *Uninstall TaskbarStats*, or *Settings* → *Apps*. The uninstaller removes the autostart task and asks (Yes/No) whether your settings and usage log in `%AppData%\TaskbarStats` may be removed as well.

Portable use (for example on a USB stick)

Create an empty file `portable.txt` next to `TaskbarStats.exe`. Settings, themes, language files and logs then live in the `data` folder next to it and nothing is written to `%AppData%`.

Building it yourself

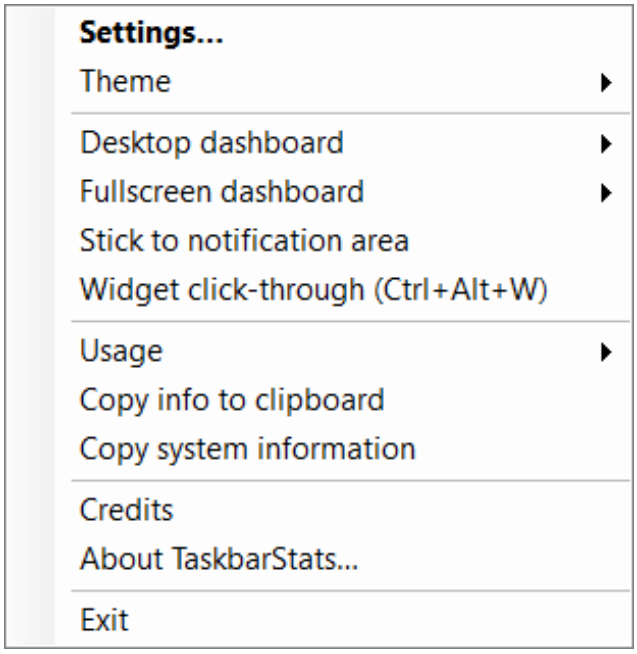

With the .NET 8 SDK installed, double-click `build.bat` (it closes the running app, builds Release and starts it again). Manually:

```
dotnet build -c Release          # exe: bin\Release\net8.0-windows\TaskbarStats.exe
build-installer.bat              # self-contained publish + Inno Setup -> installer\Output
```

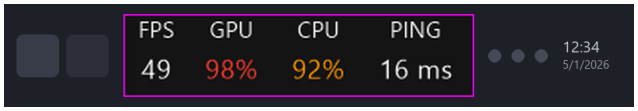

3. Using the widget

The widget is a floating window owned by the taskbar, so it stays neatly on top of it. Everything you can do with it:

Action	What happens
Drag (left mouse button)	Moves the widget, also outside the taskbar. The position is remembered. *Lock position* fixes it.
Right-click	Opens the menu (see below).
Hover (≥ 2 s, adjustable)	Tooltip with all details: CPU + clock speed, every GPU with VRAM, RAM in GB, heaviest programs, network per adapter with today's usage, disks and free space, temperatures.
Double-click	Opens Task Manager by default (adjustable).
Middle mouse button	Copies all tooltip information to the clipboard (adjustable).
Ctrl+Alt+W	Click-through: the widget stays visible, but your clicks go straight through it.

The right-click menu: short, and it stays open while you choose.

The compact widget (labels on top, narrower).

The menu

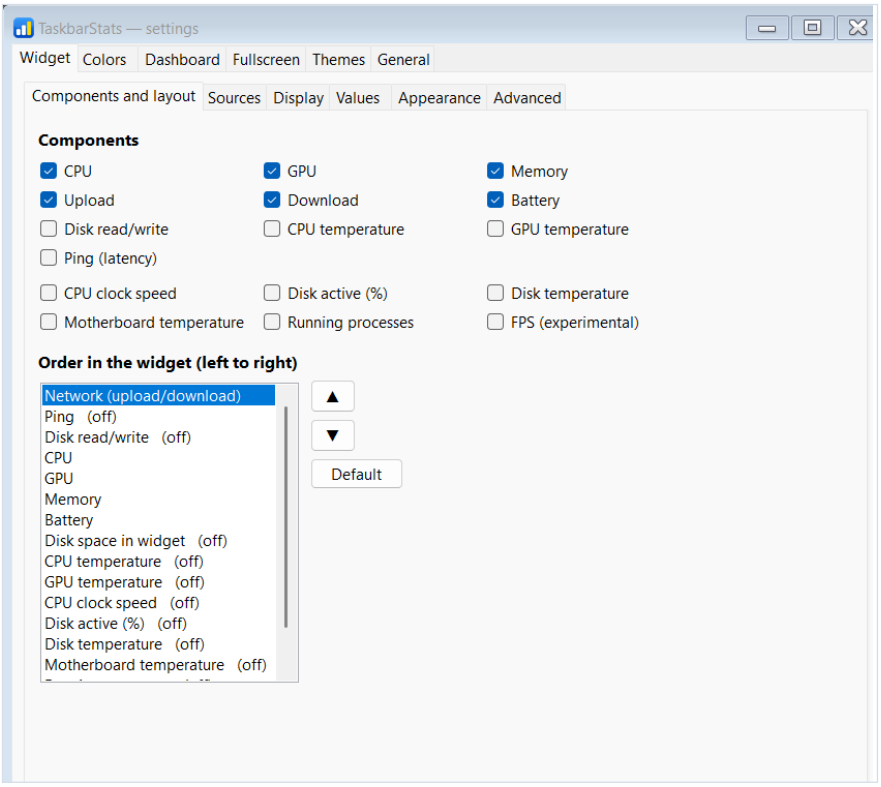

- **Settings...** (bold, at the top): the settings window with tabs.
- **Theme**: quick pick to apply a theme with one click.
- **Desktop dashboard** and **Fullscreen dashboard**: each a submenu (show, click-through, lock, settings; fullscreen: open, tour, settings).
- **Stick to notification area**, **Widget click-through**.
- **Usage**: received/sent per network adapter (session, today, yesterday, 7 days, month) and the daily log with CSV export.
- **Copy info**, **Copy system information**, **Credits** (a calm end-credits roll with a few numbers from your own usage), **About** (with a button for the welcome screen) and **Exit**.

> **Tip** The menu stays open when you click an option, so you can change several things in a row. It closes when you click outside it, press Esc, or when the mouse has been away from the menu for about a second.

Only one instance runs at a time. If you start the app a second time, the running app opens its settings window.

4. The settings window

Every change is **applied and saved immediately**; you see the result at once on the widget, the dashboard and fullscreen. Controls that have no effect because of another choice are greyed out, with an explanation why. Settings of components that are currently off (for example the GPU) can be filled in already.

Settings → Widget → Components and layout.

Tab	What you set there
Widget	Subtabs: **Components and layout** (on/off and order with the arrow buttons), **Sources** (which GPU or automatic, which network adapter or all, disks, network drives, ping target), **Display** (number / gauge / bar / graph per item, per core, labels on top, compact, transparent), **Values** (formatting, processes, FPS), **Appearance** (font, size, height), **Advanced** (graph length, period, CPU measure, refresh rate).
Colors	Text, background, gauge/bar, warning, critical, border and thresholds (for example 85% / 95%). Optionally follow the Windows theme.
Dashboard	Show, front/back, click-through, lock, opacity, scale 50-300%, 1-4 columns, order and on/off per tile, background image.
Fullscreen	Which screen, order and on/off per tile (with a thumbnail of the layout), tour time, network tile per connection type, background.
Themes	16 built-in themes, save/load/import/export your own, JSON editor, preview (10 s).
General	Language, start with Windows, lock/stick position, hide in fullscreen apps, mouse actions, tooltip delay, notifications, monthly limit, update check, backup.
Plugins	Only visible when the plugins are installed (see chapter 8).

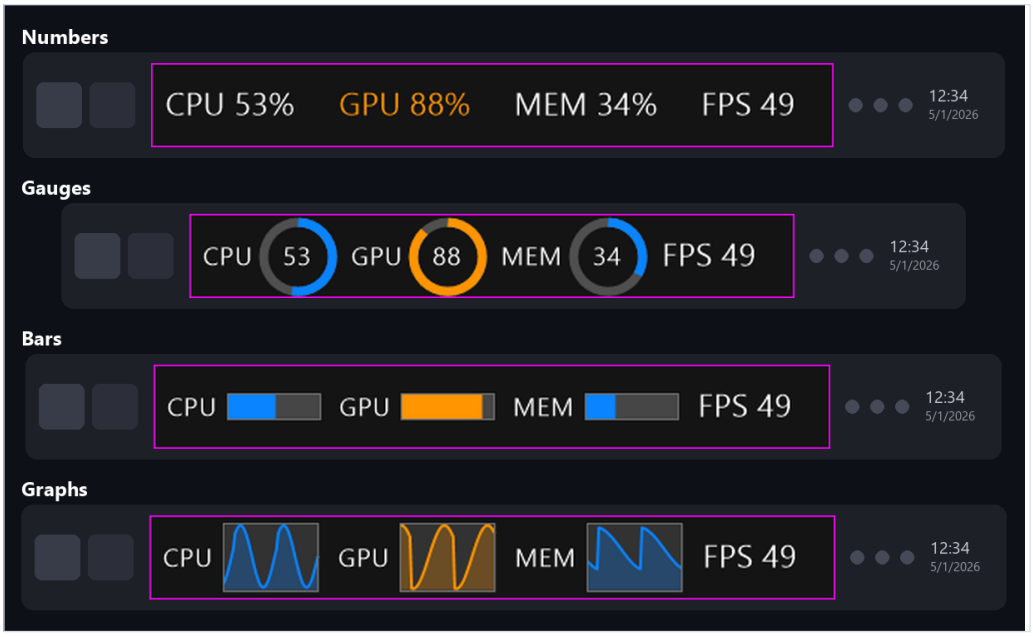

Widget components

CPU, GPU, memory, upload, download, battery (laptops), disk read/write, CPU and GPU temperature, ping, and the extras: CPU clock speed, disk active (%), disk temperature, motherboard temperature, process count and FPS. You set the left-to-right order with the arrow buttons. Disk and motherboard temperature read sensors (administrator needed) and disappear by themselves when the PC offers no value.

Notifications and monthly limit

TaskbarStats shows a notification when the battery is almost empty (20% and 10%), a disk is almost full, CPU/GPU/memory stays critical for too long, or you reach 80% and 100% of your monthly network data limit. Extra thresholds (0 = off): CPU, GPU and disk temperature, memory use and network usage per day.

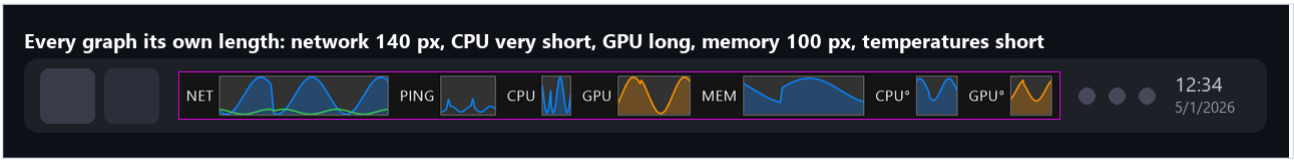

5. Display: styles, graphs and values

Four display styles: numbers, gauges, bars and graphs - selectable per item.

Graphs

CPU, GPU, memory, temperatures, network (download and upload as two lines) and ping can be shown as a mini graph in the widget, covering the last 30, 60 or 120 seconds. Missing pings break the line with a red dot. The **length** is *very short*, *short*, *medium*, *long* or a custom width; it can differ per item (Settings → Widget → Advanced → *Graph length per item*, 16-160 px).

Every graph with its own length: network wide, CPU very short, memory 100 px.

Temperature

CPU and GPU temperature can be shown as a number, gauge or bar, or **small after the CPU/GPU cell** (for example `CPU 33% 55°`) when you want to save space.

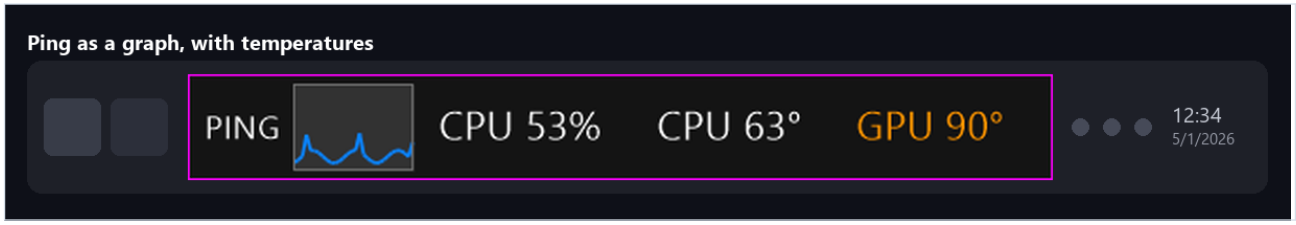

Temperature as number, gauge, bar or merged with the CPU/GPU cell.

Value formatting (Settings → Widget → Values)

- Network speed in bytes (MB/s) or bits (Mb/s), automatic or fixed unit.
- Short values; leave out the unit or %-sign; swap upload and download.
- Memory as a percentage, used (GB) or available (GB).
- Disk read/write as `R / W` or as arrows (↓ read, ↑ write) - everywhere in widget, tooltip, dashboard and fullscreen.

Ping

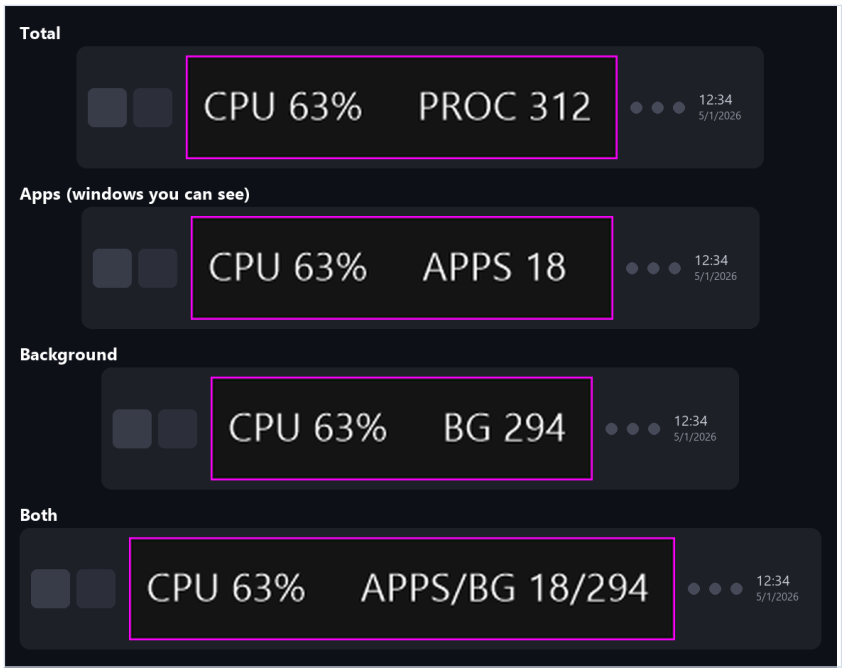

Turn on *Ping (latency)* and the widget shows for example `PING 12 ms` (orange from 100 ms, red from 250 ms or when there is no reply). The target (default 1.1.1.1) is adjustable. The tooltip and the network details in fullscreen show min/average/max, jitter and packet loss over the last two minutes.

Widget with ping and temperatures.

Processes

The number of running processes as `PROC 250`, or only the **apps** (processes with a visible window, like Apps in Task Manager), only the **background processes**, or both (`APPS/BG 5/245`). The tooltip also shows the thread count.

Processes: total, apps, background or both.

Background image and Windows theme

Per window (widget, dashboard, fullscreen) you can pick a png/jpg/bmp as background with mode *Fill*, *Stretch*, *Fit*, *Tile* or *Center* and an opacity of 0-100%. Under *Colors* the widget can **follow the Windows theme**: dark/light, optionally with the Windows accent colour for gauges and bars.

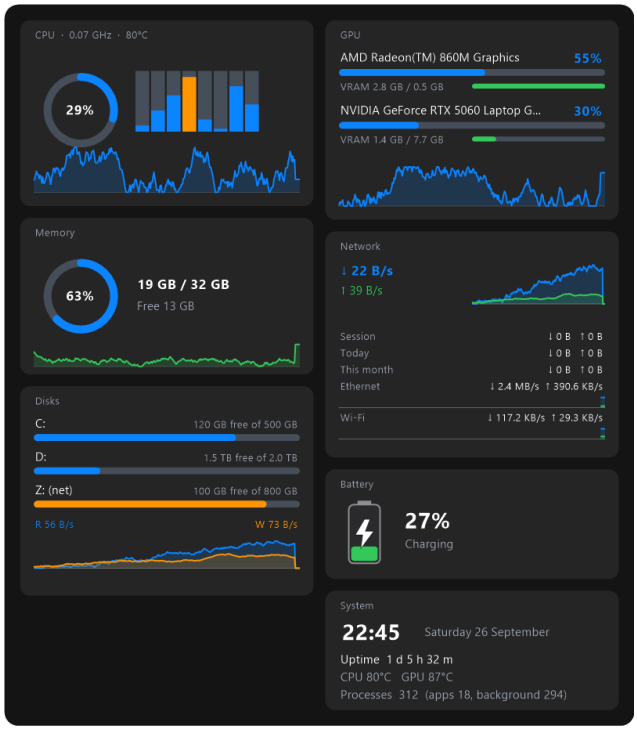

Widget with a background image.

6. Dashboard and fullscreen cockpit

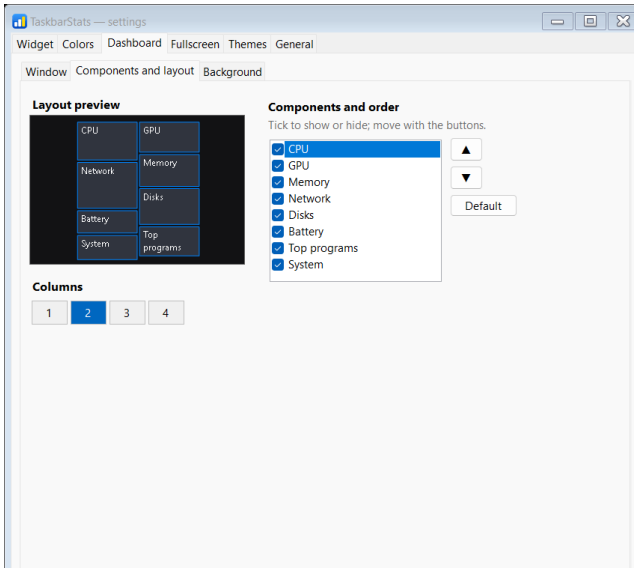

Desktop dashboard

A large, translucent window with tiles for CPU (with bars per core), GPU per card with VRAM, memory, network (mini graph per adapter), disks, battery, heaviest programs and system. It is off by default: turn it on from the menu or *Settings → Dashboard*.

- In front or behind, scale 50-300%, opacity, 1-4 columns, lock.
- **Click-through** (**Ctrl+Alt+D** or double-click the icon next to the clock): your clicks go through it, so it works like a living wallpaper. Because right-clicking no longer works then, these are the ways to turn it off again.
- The dashboard restores itself when you use *Show desktop*.

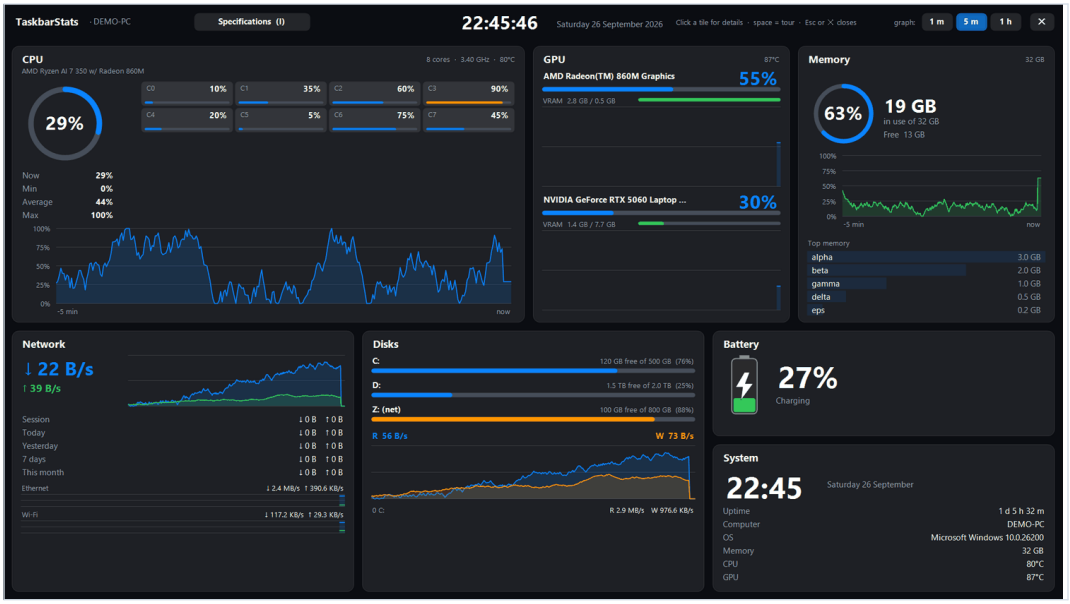

The desktop dashboard.

Settings → Dashboard: order and on/off per tile.

Fullscreen cockpit (Ctrl+Alt+F)

One dense overview of everything across a whole screen (you choose which). Click a tile for the in-depth view: graph up to 1 hour, min/average/max, per core, per GPU with VRAM, per adapter, per disk, top programs and system info.

The fullscreen overview.

CPU details.

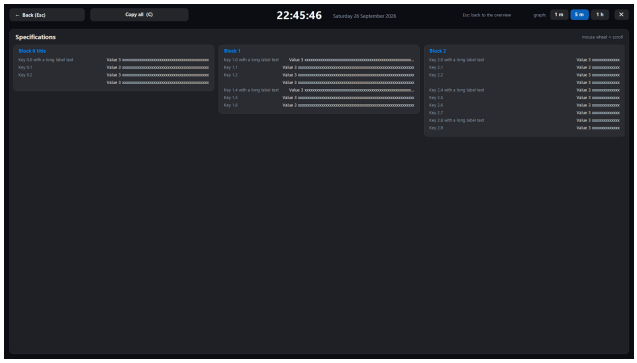

GPU details with sensors.

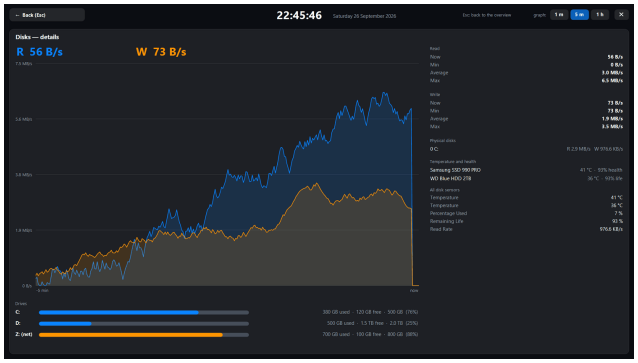

Key / action	Function
Esc	One step back; from the overview it closes the screen.
1 / 2 / 3	Graph period: 1 minute / 5 minutes / 1 hour.
I (or button at the top)	Specifications page.
C (on the specifications page)	Copy everything to the clipboard.
Space, or click 3× on an empty spot	Start the automatic tour; a click or key stops it.
Mouse wheel	Scroll (specifications, sensors).

Specifications and sensors

The specifications page shows computer, motherboard and BIOS, Windows, processor (cores, clocks, cache, instruction sets), graphics cards (driver, VRAM, outputs), memory modules, disks (type, health, firmware), displays, network adapters, battery (wear, charge cycles), security (Secure Boot, TPM), audio, input devices, Bluetooth and USB. The detail pages show sensors via LibreHardwareMonitor: CPU power, temperatures and clocks, GPU temperature/power/fan, disk temperature and SMART health, motherboard, fans, memory and battery. These sensors are only active while the fullscreen screen is open.

The specifications page (key I).

Disk details with temperature and health.

Automatic tour

Click 3× on an empty spot in the fullscreen screen (or press the space bar): the screen walks through all pages (overview, every detail, specifications). The time per page (default 10 s) is set via the menu (*Fullscreen tour*) or under *Settings* → *Fullscreen*. Handy on a second monitor as a permanent info screen.

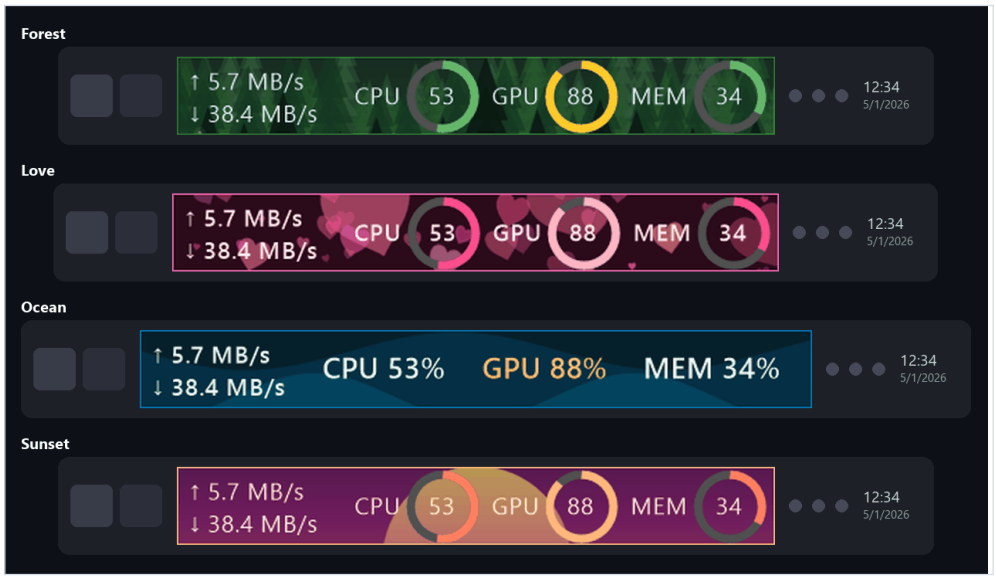

7. Themes and gamers

Themes

A theme is a small JSON file with style, colours, font, height and the layout of dashboard and fullscreen (no screen positions and no language). **16 are built in**: Default, Dark, Light, Black & white, Love, CGA, Matrix, Amber, Game Boy, Dracula, Ocean, Sunset, Forest, Minimal, Gauges and Neon. Some have their own background drawn in code (falling Matrix characters, Neon grid, sun, stars, waves, hearts, pine forest with fireflies, scanlines).

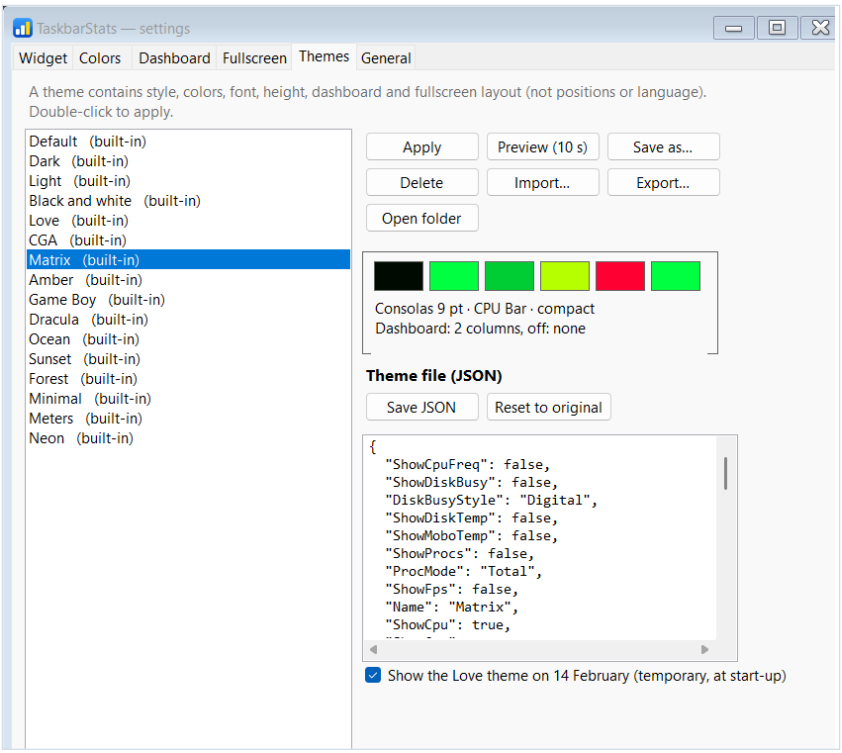

The built-in themes, here with FPS in the widget.

Widgets with the theme backgrounds.

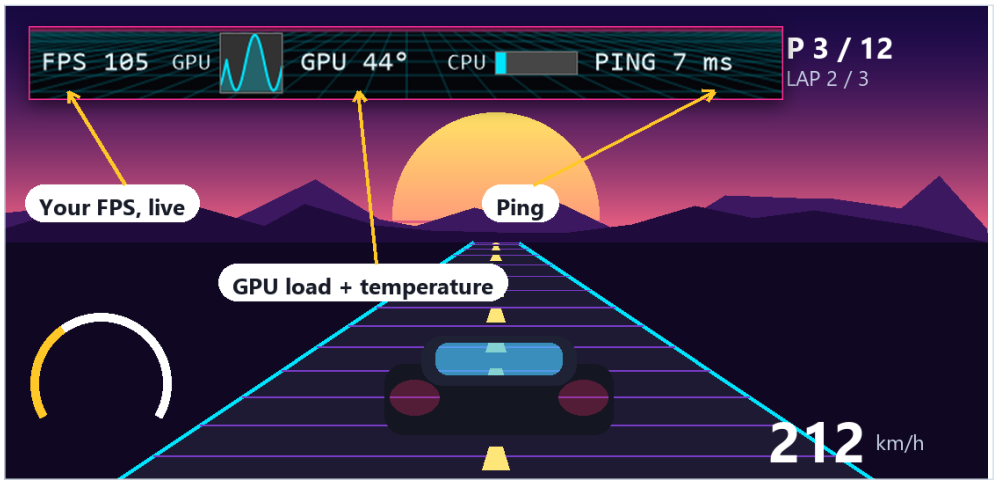

- **Preview (10 s)**: the chosen theme (or the JSON in the editor, even unsaved) is shown for 10 seconds on widget, dashboard and fullscreen with rising and falling values and changing display styles. Afterwards everything returns to how it was.
- **JSON editor**: under *Themes* you see and edit the JSON of the chosen theme; on an error you get the line and position. You can also edit a built-in theme this way (*built in, modified*); **Reset to original** removes your version again.
- **Sharing**: export a theme and hand over the file; the other person imports it. Your own themes live in `%AppData%\TaskbarStats\themes\`.
- On **14 February** the app temporarily starts with the Love theme (in memory only; your own look is kept). You can turn this off under *Themes*.

Settings → Themes.

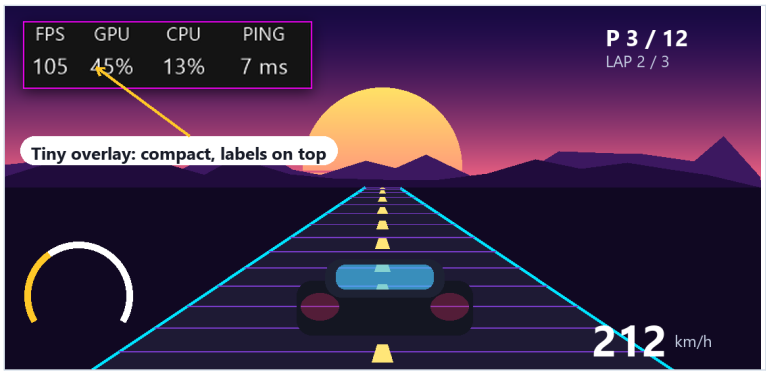

For gamers

Turn your taskbar into a free FPS counter, or drag the widget over your game.

FPS, GPU load and temperature, CPU and ping floating over a game.

- **FPS** (experimental): measured like PresentMon, using Windows event tracing of the foreground program. Works with DirectX games (DXGI/D3D9), Vulkan (via DxgKrnl) and browsers. Turn it on under *Settings → Widget → Values*. Only a process id and timestamp are counted, no content. The tooltip also shows the **1% low** and the program.
- **Mini overlay**: compact, labels on top, only FPS, GPU and CPU.
- **Click-through** (Ctrl+Alt+W): the widget stays visible, mouse clicks go to the game.
- Turn *Hide in full screen* off if the widget should stay visible above a game.

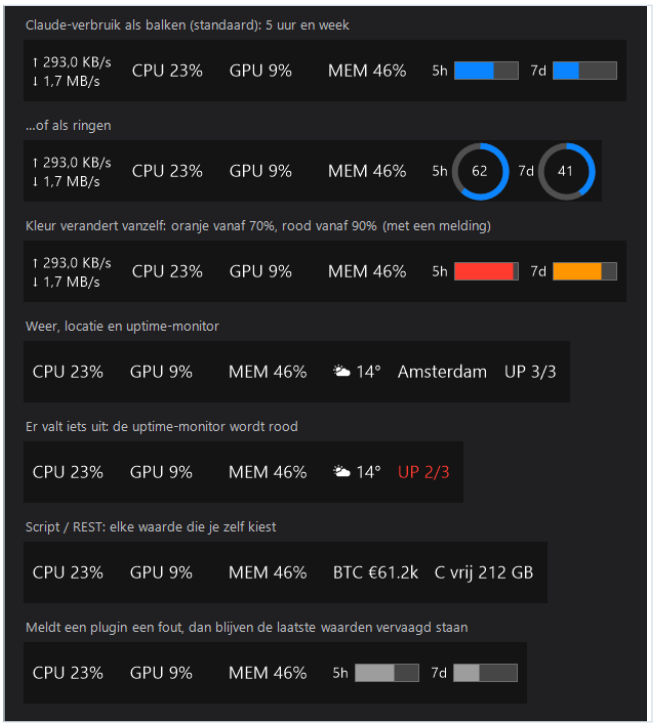

Mini overlay over a game.

8. Plugins (optional)

Plugins add extra values to the widget, the dashboard and fullscreen. They are off by default and are installed through the optional step *Optional plugins* in the installer (silent: `/TASKS="plugins"`). Then you turn them on under *Settings → Plugins*.

Plugin	Shows	Data from
Claude usage	% of your 5-hour and weekly limit used and the time until it frees up (bar, ring or number; notification at the limit)	The Claude Code sign-in on your PC (read only), sent to Anthropic (undocumented address)
Weather	Sun/clouds/rain, temperature, humidity, wind, chance of rain	Open-Meteo (free, no key); only coordinates are sent
Location (GPS)	Place name, coordinates, accuracy, source, distance from home	Windows location service, otherwise your IP address
Uptime monitor	"3/3" up; red plus a notification when something goes down	Your own list of websites (HTTP), ports (TCP) and devices (ping)
Script / REST	Any value you choose	A command, text file or JSON web address: Home Assistant, NAS, exchange rate, ...

Plugin examples in the widget.

Why it is safe

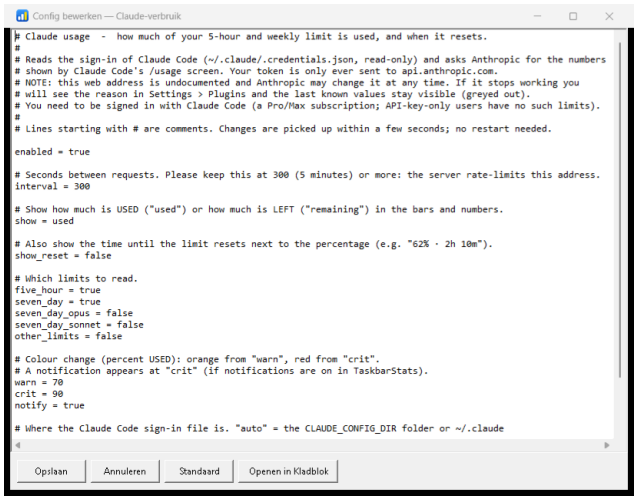

TaskbarStats runs as administrator and therefore **never executes plugin code**. The plugins run in a separate helper (`TaskbarStats.Plugins.exe`) that starts through a scheduled task **without administrator rights** and writes one small JSON file per plugin to `%AppData%\TaskbarStats\plugins\`. The app only reads those files. The helper stops by itself when TaskbarStats closes or no plugin is on.

Setting up

- **Edit config…** opens a simple editor for the plugin's `.ini` file (`key = value`; the comment lines explain every option). Changes take effect within seconds; *Default* restores the original text.
- Under **Values** you choose per value: in the widget or not, text, bar or ring, and a colour.
- Dashboard and fullscreen have the **Plugins** tile; it only appears when there is something to show. In fullscreen it is a strip at the bottom; click it for the detail page.

The Plugins tab.

The config editor.

> **Note** For **Claude usage** you must be signed in with the Claude Code CLI (`claude`, then `/login`). The Anthropic address it uses is undocumented and may change; the plugin then shows the reason and keeps the last values faded. Your token only goes to api.anthropic.com and is never written to a file or log.

Your own plugin, in any language

Write a file `%AppData%\TaskbarStats\plugins\<name>.json` and write it again whenever the value changes. `ttl` is the number of seconds before a value is shown faded (stale), `level` is `ok`, `warn` or `crit`, and `notify: true` gives a notification at `crit`. It appears by itself under *Plugins → Values*.

```
{
  "plugin": "mytool", "title": "My tool", "updated": "2026-11-07T10:00:00Z", "ttl": 600, "status": "ok",
  "items": [
    { "key": "queue", "label": "Build queue", "short": "Queue", "value": 3, "min": 0, "max": 10,
      "unit": "", "text": "3 jobs", "detail": "last run 10:31", "level": "ok", "widget": true, "notify": false }
  ]
}
```

9. Tips and tricks

Shortcuts and mouse

Shortcut / action	Function
Ctrl+Alt+D	Dashboard click-through on/off
Ctrl+Alt+F	Open/close the fullscreen cockpit
Ctrl+Alt+W	Widget click-through on/off (also via the icon next to the clock)
Esc (fullscreen)	Back / close
1 / 2 / 3 (fullscreen)	Graph 1 min / 5 min / 1 hour
I / C (fullscreen)	Specifications / copy everything
Space or 3× click (fullscreen)	Automatic tour
Double-click / middle-click on the widget	Task Manager / copy tooltip (changeable under *General*)

Handy tricks

- **The menu stays open** - Click several options in a row; the menu only closes when you click outside it, press Esc or the mouse is away.
- **Widget lost or crooked?** - Choose *Stick to notification area* in the menu: the widget moves next to the notification area and follows it when that moves. Dragging turns it off again.
- **Test-drive a theme** - Use *Preview (10 s)* instead of choosing right away: you see the theme in all styles and everything jumps back by itself.
- **Wallpaper with numbers** - Put the dashboard on *background* + *click-through* (Ctrl+Alt+D) with a nice theme and a background image.
- **Save space** - Use *Compact*, put the temperature small after the CPU/GPU cell and pick short graph lengths per item.
- **Two GPUs** - Leave the GPU on *Automatic*: the busiest one counts, and every GPU gets its own colour so you see which one the number belongs to. To follow just one, pick a fixed GPU under *Sources*.
- **Network in bits** - Providers quote Mb/s: choose bits instead of bytes under *Values*.
- **Compare with Task Manager** - You can switch the CPU measure to *Utility*; that is roughly what some tools show, but on a boosting CPU it is almost twice as high as Task Manager.
- **Help for support** - On the specifications page, key **C** copies all specifications as plain text - ideal for a forum post. In *About*, *Copy diagnostics* copies the version, Windows and the last log lines (without user or computer name).
- **New PC?** - *Settings* → *General* → *Backup*: export all your settings to one JSON file and import it on the other PC. You can also reset to defaults (themes and usage log stay).
- **Info screen** - Fullscreen on a second monitor with the automatic tour makes a fine permanent info screen.
- **Share a theme** - Export a theme and email the file; the other person imports it. Everything the app exports or copies mentions the program and its link.
- **Your own language** - Put a language file in `%AppData%\TaskbarStats\lang\` and restart the app. With `TASKBARSTATS_PSEUDO=1` and the language *Pseudo (test)* you see at once which texts are untranslated or too long.

- **Network drives** - Turn on *Include network drives* under *Sources*; they are queried in the background, so an unreachable share does not slow the app down.
- **Home Assistant, NAS, exchange rate…** - Use the *Script / REST* plugin: a command, text file or JSON web address can put any value you want on the widget.

> **Tip** Want the app to never touch the internet? Leave the plugins and the update check off: then TaskbarStats only uses the network to measure usage and ping.

10. Troubleshooting

Problem	Solution
The menu or tooltip does not appear	Click the widget first and try again.
The widget is off-screen	Start TaskbarStats from the Start menu, then right-click → *Stick to notification area*.
No temperatures	The app must run as administrator (default). If your processor has no CPU sensor, the app uses the Windows thermal zone. Some sensors (like the motherboard) do not exist on every PC.
GPU value looks wrong	Pick a fixed GPU under *Sources* instead of *Automatic* and compare with the 3D engine in Task Manager.
FPS stays empty	FPS is experimental, off by default and needs administrator rights. A value only appears while a program is drawing frames (game, video player, browser).
A UAC prompt at logon	Use *Start with Windows* (scheduled task with highest privileges) instead of your own shortcut in Startup.
Defender reports a vulnerable driver (Winring0)	That happened with old versions (1.6.0-1.6.3). Update to 1.6.4 or newer: it contains no driver any more.
The Claude plugin shows no numbers	Sign in with the Claude Code CLI (`claude`, then `/login`). Claude's connector file is never used.
Usage is not completely right	Traffic while the app is not running is not counted.
The app crashed	On the next start a balloon notification appears; click it for the About screen with *Copy diagnostics*. Errors are in `diag.log` in the data folder - on your own PC only.
Taskbar restarts or Explorer crashes	The widget notices a new taskbar and attaches itself again; if not, close the app and start it again.

Where is my data?

File / folder	Contents
`%AppData%\TaskbarStats\settings.json`	Your settings (survives rebuilds and reinstalls)
`%AppData%\TaskbarStats\usage.json`	Network usage per day
`%AppData%\TaskbarStats\themes\`	Your own themes
`%AppData%\TaskbarStats\lang\`	Custom language files
`%AppData%\TaskbarStats\plugins\`	Plugin output and configs
`%AppData%\TaskbarStats\diag.log`	Error log (stays on your PC)
Portable: `data` folder next to the exe	Everything above, when `portable.txt` sits next to the exe

> **Tip** TaskbarStats sends no data to the developer. Only the optional plugins (weather, location, Claude usage, uptime, REST) and the optional update check connect to the internet, and only when you turn them on.

11. Licence, credits and contact

TaskbarStats is free to use under the **MIT licence**: you may use, modify and share it, also in your own projects. The only condition is that the copyright line and licence text are kept - so please leave the credits in.

Idea, design and testing by Eric Bruggema. **Built with** Claude Code (Anthropic).

Third-party software	Licence	Used for
LibreHardwareMonitorLib	MPL-2.0	Temperature and other sensors
HidSharp	Apache-2.0	Device communication
.NET 8 / Windows Forms	MIT	The program itself
Inno Setup	Inno Setup License	The installer

These components remain under their own licences.
